Special Feature

By leveraging the proprietary technology we have accumulated over many years with technologies acquired through M&A activities, we are working to

Become a Top Global Supplier in the Field of Superconductors.

Furukawa Electric has conducted R&D in the field of superconductors since the 1960s, and has amassed some of the world’s leading technologies in this sector.

In February 2012, we acquired SuperPower Inc. of the United States, one of only a few companies in the world currently manufacturing second-generation high-temperature superconductor wire materials. We converted this company to a subsidiary in order to bolster our competitiveness in world markets.
Successes Based on a Half Century of R&D Have Led Us to Possess Some of the World’s Leading Technologies in the Superconductor Field.

Against the backdrop of increasingly severe global warming and electric power risks, throughout the world interest has grown in the practical application of superconductor technologies to use energy more effectively. Since the 1960s, Furukawa Electric has the leading role in R&D of superconducting technologies. Over that time, our efforts have included the spectrum of activity from low-temperature superconductivity using metallic materials to high-temperature conductivity with oxide materials. In the process, we have accumulated some of the world’s leading technologies in this field.

Furukawa Electric’s Efforts

- **1963**
  Commenced R&D on low-temperature superconductivity
  Began industrial production of NbTi multicore wire

- **1971**
  Phenomenon of superconductivity first discovered at Leiden University in the Netherlands, using mercury

- **1953**
  Nb3Sn discovered to be a practical metallic superconducting material

- **1957**
  BCS theory proposed to explain superconductivity

Worldwide Evolution of Superconducting Technologies

- **1911** Phenomenon of superconductivity first discovered at Leiden University in the Netherlands, using mercury
- **1953** Nb3Sn discovered to be a practical metallic superconducting material
- **1957** BCS theory proposed to explain superconductivity

- **1963** Commenced R&D on low-temperature superconductivity
- **1973** Became the first in the world to succeed in producing ultrafine multicore wire using a compound of V3Ga and Nb3Sn
- **1980** Constructed a large-scale accelerator, developed a model coil for research into nuclear fusion, conducted superconducting generator verification testing and participated in other large-scale projects in Japan and overseas
- **1986** Commenced R&D into high-temperature superconductivity

- **1983** The European Organization for Nuclear Research (CERN), which announced the discovery of the Higgs particle to a high degree of certainty in July 2012
- **1982** Golden-Hadron Award: Prize awarded by CERN to manufacturers determined to have contributed substantially to the LH2 plan
- **1981** NEDO “Project for the Development of a Technological Base for the Application of Superconductivity”

- **2003** Delivered cables for the Large Hadron Collider at CERN®, becoming the first company in the world to provide detection equipment for large-scale conduction
- **2005** Based on this performance, won the Golden Hadron Award®
- **2007** Performed field test on 500 m superconducting cable, the longest in the world at the time, at the Central Research Institute of Electric Power Industry®
- **2009** Achieved the world’s lowest transmission loss through application of ultrafine wire processing technology and cable forming technology that reduces the perpendicular magnetic field®
- **2011** Developed the world’s highest-voltage 275 kV superconducting cable®
- **2012** Through the acquisition of a U.S. company, became the world’s only integrated manufacturer of second-generation high-temperature superconducting materials
- **2011** Marked the 100th anniversary of the discovery of the phenomenon of superconductivity
- **2015** Ceremonies held in Japan and overseas

Commenced Verification Testing in China of the World’s Highest-Voltage Superconducting Cable

In the Chinese city of Shenyang, the Furukawa Electric Group will conduct long-term loading cycle tests of the world’s highest-voltage 275 kV superconducting cable in October 2012. This test was commissioned by the New Energy and Industrial Technology Development Organization (NEDO) as part of its “Technological Development of Yttrium-based Superconducting Power Equipment Project.” By conducting verification testing in China, where demand for transmission infrastructure is rising sharply, we aim to demonstrate the technological superiority of superconducting cables and enhance our international competitiveness.
Meeting Expanding Demand for Superconductivity in Regions throughout the World by Using Smart Grids as Key Materials

Now that a century has passed since the phenomenon of superconductivity was first discovered, technological development and commercialization is accelerating. In particular, attention is focusing on the use of smart grids, which are anticipated for use in next-generation social infrastructures. By adding the second-generation high-temperature superconductor (2G HTS) wire production technology of SuperPower, Furukawa Electric plans to reinforce its lineup of technologies aimed at realizing smart grids. We provide advanced technologies and products in a host of fields related to the generation, transmission and storage of electricity.

**Lowering Transmission Loss**

We help to transmit the electricity that power plants generate in a stable manner and without losses.

The electrical resistance of power cables means that some energy is lost when electricity is sent from power stations to locations where the power is used. In Japan, where reducing the use of electricity has become an important issue for society as a whole, approximately 5% of power is lost during transmission.

Cables that use superconducting technologies have no electrical resistance, so transmission losses are greatly reduced. By 2050, we estimate that approximately 4,000 km of copper cable will be replaced with superconducting cable, reducing annual power consumption by 3.1 billion kilowatts for every 2.6 million people. This equates to a decrease in the CO₂ emitted during generation of 1.06 million tons (based Furukawa Electric’s calculations).

Combining SuperPower’s technologies in the mass production and lengthening of 2G HTS materials with Furukawa Electric’s technologies in power cables will enable the mass production of superconducting cables of higher quality and at a lower price. This combination should enable us to meet increasing global demand.

**Superconducting Cable Demand Forecast**

(based Furukawa Electric’s calculations)

Storing Large Amounts of Electricity without Losses

We are using superconducting magnetic energy storage (SMES) to stabilize supply and demand for electric power.

To encourage the spread of generation from renewable energy sources such as solar and wind power, systems are needed to store excess energy and thereby offset natural fluctuations. Rapid charging and discharging was difficult for the storage batteries used in the past, so the industry was unable to overcome generation irregularities.

SMES, which allows large amounts of electricity to be charged and discharged instantaneously, can help to offset power fluctuations in real time. As a result, this technology is a subject of growing attention for use in electricity storage equipment at renewable energy generation facilities.

SuperPower’s 2G HTS wires are ideal for the coils needed to generate the strong magnetic fields required by SMES. Therefore, we are collaborating with ABB, the University of Houston and Brookhaven National Laboratory to develop SMES systems.

Raising Generation Efficiency

By raising generation efficiency and making generation equipment more compact and lightweight, we are contributing to the proliferation of wind power generation.

Wind power generation is a type of sustainable energy use that is gaining popularity throughout the world. At present, the largest wind power generators are around 5 megawatts in scale. Technological developments will be needed to increase this amount to 10 or 15 megawatts. With conventional technologies, increasing the amount of power generated required larger generators, which led to higher manufacturing and construction costs. However, using 2G HTS wire, which has zero electrical resistance and high current density, means that even very thin wires can transport a large amount of electricity. This situation results in more efficient generation and more compact and lightweight generation equipment.

At present, SuperPower is cooperating with TECO-Westinghouse and the University of Houston on research and development of 2G HTS wire for large-scale wind power generators of around 10 megawatts. Around the world, rising expectations are accelerating the uptake of large-scale wind power generation including conducting research that will contribute to the reduction of CO₂ emissions and the use of oil resources.
Through the Acquisition of SuperPower, Becoming the World’s Only Integrated Manufacturer of Second-Generation High-Temperature Superconductivity Wire

Only two companies in the world are capable of mass producing second-generation high-temperature superconductor (2G HTS) wire. Furukawa Electric has acquired one of these, SuperPower, thereby turning the Company into the world’s only integrated manufacturer of 2G HTS wire.

In this section, SuperPower’s President Shirasaka, assigned from Furukawa Electric, and heads of the company’s management and sales divisions talk about synergies and the benefits of collaboration between SuperPower and Furukawa Electric.

Combining SuperPower’s Wire Production Technology with Commercialization Capabilities Developed by Furukawa Electric

Yusei: The most significant element in this acquisition was the addition of the 2G HTS wire production technologies possessed by SuperPower to the lineup of superconducting technologies that Furukawa Electric has cultivated over many years. As 2G HTS wire using rare earth-based elements can be produced at a lower cost than bismuth-based first-generation materials, they are gaining attention as the mainstream superconducting material of the future. However, as the technological hurdles to producing 2G HTS wire are high, only two companies in the world are currently capable of producing it in mass quantities. By adding one of these companies to the Furukawa Electric Group, we have become the only corporate group in the world able to supply mass quantities both 2G HTS wire and HTS-based equipment.

Art: I understand that Furukawa Electric has conducted research over a long period of time, from the era of low-temperature superconductivity. SuperPower’s predecessor manufactured metallic superconductor wires as well, so I believe we have some points in common. If we can integrate the 2G HTS wire production technologies that SuperPower possesses with Furukawa Electric’s technologies in power cables, wound wires and equipment development, we should be able to provide even more advanced superconductor materials to world markets.

Trudy: On the sales front, Furukawa Electric’s global markets.

For a company to succeed, I believe that respect for student interns.

Museum, where I am vice president of the board of trustees. We partner with local schools and universities to contribute in many ways to the local community. I am on

Yusei: The social contribution front, in addition to the technology likely to be sources of encouragement to each other on backgrounds, which leads to the development of more diversity is important. The engineers at our company come from a range of different cultures and backgrounds.

Art: I believe that companies to the Furukawa Electric Group have been active in CSR activities for some time; what is the situation at SuperPower?

Meeting Our Corporate Responsibilities and becoming a Trusted Corporate Group in Global Markets

Yusei: Being active in global markets requires competitive technologies and products; it also requires that a company be trusted by society. Furukawa Electric has been active in CSR activities for some time; what is the situation at SuperPower?

Trudy: Our headquarters and manufacturing operation are located in Schenectady, New York, and we contribute in many ways to the local community. I am on the board of directors of the Schenectady chamber of commerce. In 2010, the 10th anniversary of SuperPower’s founding, we built and contributed an exhibit about superconductivity to the Schenectady Museum, where I am vice president of the board of trustees. We partner with local schools and universities to promote education in the area of superconductivity, including teaching courses in the field and hosting student interns.

Art: For a company to succeed, I believe that respect for diversity is important. The engineers at our company come from a range of different cultures and backgrounds, which leads to the development of more innovative technologies. The company also has two female managers, in addition Trudy, who is a company director.

Yusei: This is excellent. I am pleased to hear that we are likely to be sources of encouragement to each other on the social contribution front, in addition to the technology and business sides.
